The uninformed person who is seeking out steroids on the underground market is taking huge risks. Even those who are aware of the risks and knowledgeable about the actions of the different anabolic steroids are taking a big chance if they purchase them from the underground. Anabolic steroids, in truth, are not meant to be used to improve an athlete's performance. Parabolan is one steroid that has properties from two different classifications: anabolic and androgenic. This is a powerful compound that is five times more powerful than testosterone. Parabolan both increases the muscle mass and burns the fat of the athletes who use it. This makes it very popular with body builders. In the interest of muscle growth, this chemical acts to decrease catabolism. The breakdown and release, as energy, of the protein in the muscle mass is a result of catabolism. Parabolan inhibits catabolism, which is preferable to body builders who wish to keep the protein in their muscles. So anything that inhibits catabolism will be desirable for bodybuilders. Parabolan is called a "nutrient partitioning agent." What this means is that from the foods a body builder eats, less will be converted into fat and more into muscle. The oral administration of anabolic steroids - via pill - is the most common method of delivery. The pill form is also, as a rule, much easier to come by. The extreme downside to oral ingestion is that this is the type that carries the greatest risk for developing serious side effects. Another highly desirable outcome of oral steroids is they are fast acting. One more positive advantage, only to the user, is the oral variety will leave the system much faster than the injection-based steroids. Be that as it may, in the sports industry, it is not uncommon for higher-echelon athletes to take the steroids in both pill form and as an injection.
